Feature and screen guide

Every screenshot taken from the working system

What the system does, and what it fixes

The problem

Four groups of people work a restaurant at the same time, on four different kinds of device, all needing the same information. The gaps between them — a lost ticket, a miscounted bill — are what cost the business money.

- **Orders stop getting lost**
The moment a server confirms an order it appears on the kitchen screen — no paper tickets, no shouting across a busy service.
- **Every bill adds up correctly**
Discounts, service charge and VAT are applied identically every time, and split payments need no calculator.
- **You see the numbers while the day is still running**
Sales, busiest hours and best sellers update as bills close, not at month end.

Who uses what

Role	Device	Day-to-day use
Servers	Phone or tablet	Floor plan · take orders · mark served
Kitchen	Tablet or wall screen	Live ticket queue, no printer needed
Cashier	Tablet or computer	Take payment · discounts · receipts
Manager / Owner	Computer (web browser)	Dashboard · menu · staff · reports

03	Payment and receipts The part of service that has to be right every time.	3 screens
04	Tablet stations A larger screen removes steps from the job, not just pixels.	3 screens
05	Management and reporting The back-office work, on a computer where it is comfortable to do.	9 screens

Every screenshot in this document is rendered directly from the working system, not drawn as a mock-up. The interface shown is Thai; an English interface is available on request.

Taking orders — front of house

The screens servers touch hundreds of times a shift, built for one-handed use.

Sign in

Every shift starts here, and each person only ever sees the tools for their job.

- Five separate roles: admin, manager, server, cashier and kitchen. A server simply never sees staff records or takings.
- Accounts are created and disabled by the manager, so a departing employee loses access the same day.
- Demo accounts are included so you can try each role before committing to anything.

In practice — Permissions are enforced by the server, not just hidden in the app. Someone cannot reach a screen they are not entitled to.

Floor plan

The state of your whole dining room at a glance.

- Green means free, orange means occupied. New staff learn it in under a minute.
- Each occupied table shows the running total and how long the guests have been seated, so you can see which tables are close to paying.
- Tables are grouped by the zones you actually use, so finding a table on screen matches walking to it.

In practice — The plan updates by itself. When a colleague opens or closes a bill on another device, every screen in the restaurant reflects it within a second.

Choosing dishes

Fewer taps per order means shorter queues at the table.

- Search and category filters respond instantly, even on a weak Wi-Fi signal.
- Dishes that have run out are greyed out and cannot be ordered by mistake — the kitchen can switch them off themselves.
- Recommended dishes carry a badge, which is a simple way to push higher-margin items.

In practice — Ninety percent of orders are placed in two taps: pick the table, pick the dish.

Options and special requests

"Extra spicy, add a fried egg, no coriander" — captured exactly.

- Required choices such as spice level cannot be skipped, so the kitchen never has to chase a server for an answer.
- Paid extras are added to the price automatically, so add-ons stop leaking revenue.
- Free-text notes go straight to the kitchen ticket, highlighted so they are not missed.

In practice — You define which options exist, whether they are compulsory and how much they cost — no developer needed.

The order before it is sent

Servers can answer "how much is that?" before the food is even cooked.

- Identical items are combined automatically, so a table ordering four of the same drink reads as one clean line.
- Service charge and VAT are shown separately from the start — no surprises at the till.
- An order can be sent to the kitchen immediately, or held while the table keeps deciding.

In practice — The total shown is calculated with exactly the same rules the till uses, so the figure quoted at the table is the figure on the bill.

An open bill

Everything about one table in a single screen.

- Each dish carries its own status, so a server knows what is still in the kitchen and what is ready to carry out.
- Once the kitchen has started cooking, a dish can no longer be quietly edited or deleted — only a manager can void it. That protects both food cost and takings.
- Adding a second round to the same bill is one tap, no new bill required.

In practice — Every void is recorded against the manager who approved it.

All orders

For following what is outstanding across the whole restaurant.

- Filters follow the real working order: not yet sent, in the kitchen, all served, paid.
- Useful during a rush to spot a table that has been waiting too long.
- Closed bills from today stay available for checking a query with a guest.

In practice — The list refreshes on its own as bills move through the service.

Account and connection

Small screen, but it answers the question staff ask most: "is it still connected?"

- A green dot confirms the device is live with the rest of the restaurant.
- Shows which role is signed in, which prevents work being logged to the wrong person.
- Signing out asks for confirmation, so it does not happen by accident mid-shift.

In practice — If the connection drops, the indicator turns grey immediately rather than letting staff believe orders are being sent.

SECTION 02

The kitchen display

Replaces the printer and the paper spike — readable from across the pass.

Live ticket queue

Three columns showing the whole kitchen's workload at once.

- Tickets appear the instant a server confirms them. Nothing to print, nothing to lose.
- Any dish waiting longer than fifteen minutes turns red with a flame icon, and a counter at the top shows how many are running late. Problems surface before the guest complains.
- Guest requests are highlighted in yellow so they are never buried under the dish name.
- One large button per ticket moves it forward. There is nothing else to learn.

In practice — Waiting times update continuously without anyone touching the screen. A quiet kitchen screen genuinely means there is no outstanding work.

Kitchen view on a phone

The same queue on a smaller screen, arranged as tabs.

- Works as a backup when the main kitchen tablet is occupied or being charged.
- Useful for a prep station or a bar that only handles part of the menu.
- The kitchen can mark a dish as sold out here, and it disappears from every server's menu immediately.

In practice — Adding another screen costs nothing — it is the same application, signed in on another device.

Payment and receipts

The part of service that has to be right every time.

Taking payment

The bill on the left, the payment on the right, finished in one screen.

- Split payments are standard, not an afterthought: part on QR, the rest in cash, with the outstanding balance tracked automatically.
- Change is calculated as the cashier types, with shortcut buttons for the notes guests actually hand over.
- Overpaying a balance is simply not possible, and when the bill is settled the table is released for the next guests without anyone remembering to do it.

In practice — The outstanding balance is always recalculated from the payments actually recorded, so a bill settled in three parts still balances to the satang.

Paying at the table

The same process on a phone, for restaurants that settle bills at the table.

- Nothing is removed on the smaller screen — discounts, split payments and change all work identically.
- Change due is shown in large green type, because it is the number read aloud to the guest.
- Payments already taken against the bill are listed, so a second cashier can pick up where the first left off.

In practice — Useful for terraces and outdoor seating where walking a guest to a till is impractical.

Receipt

Laid out like a printed slip, ready for a thermal printer.

- Shows every dish with its options, then discount, service charge and VAT on separate lines — the breakdown a guest or an auditor expects.
- Lists each payment method used and the total change given.
- The restaurant name and tax rates come from your settings, so nothing has to be edited by a developer when they change.

In practice — Receipts can be reopened at any time from the order history, which settles most billing disputes in a few seconds.

Tablet stations

A larger screen removes steps from the job, not just pixels.

Order station

Menu on the left, the running order permanently visible on the right.

- No opening and closing a basket, which measurably shortens the time to take a large table's order.
- The running total stays in view, so a server can advise a group as they order.
- Well suited to a fixed station near the pass, or a counter service setup.

In practice — The layout adapts to whatever screen it finds, so the same tablets can be redeployed as the restaurant changes.

Floor plan on a tablet

The whole dining room without scrolling.

- Navigation moves to the side of the screen, where a hand holding a tablet naturally rests.
- More tables fit at once, which suits a host stand managing seating.

In practice — Column count adjusts to the screen automatically — nothing to configure.

Bill detail on a tablet

Dishes and totals side by side.

- A manager can review an entire table without scrolling, which makes checking a disputed bill quick.
- The actions that matter — send to kitchen, add dishes, take payment — sit together.

In practice — Identical to the phone version in behaviour, so staff move between devices without retraining.

Management and reporting

The back-office work, on a computer where it is comfortable to do.

Dashboard

Open it and know how the restaurant is doing right now.

- The top bar answers the operational questions: how many bills are open, how many tables are in use, how much work the kitchen still has.
- Today's takings, number of bills and average spend per bill, without exporting anything.
- The hourly chart shows when your rush actually happens, which is the basis for sensible staff rotas.
- Best sellers and the split between cash, QR and card are on the same screen.

In practice — Figures refresh as bills close, so the dashboard is accurate at any point during service rather than only after cashing up.

Sales reports

Look back over any period you choose.

- Today, the last seven days, this month, or any custom date range.
- Separates food revenue from discounts, service charge and VAT, so you can see exactly how the net figure was reached.
- Ranks dishes and summarises revenue by category — the numbers you need before changing a menu or a price.

In practice — All figures are calculated from the recorded bills, so a report can always be traced back to individual transactions.

Menu management

The one thing a restaurant changes daily: what is available.

- A single switch takes a dish off sale across every device instantly.
- A counter shows how many dishes are currently switched off, so nothing stays hidden after the delivery arrives.
- Categories are managed separately, and a category still holding dishes cannot be deleted by accident.

In practice — Kitchen staff and servers can mark items sold out themselves; only managers can change prices and details.

Adding and editing dishes

Including the option groups guests choose from.

- Set which choices are compulsory and how many can be picked.
- Give each extra its own price, so add-ons are charged consistently.
- Record an approximate preparation time for future kitchen planning.

In practice — No technical knowledge required — this is the same form used to build the sample menu in this document.

Staff accounts

Who can do what, controlled in one place.

- Filter by role and see the headcount for each at a glance.
- Change someone's role, suspend an account temporarily, or remove it entirely.
- An account cannot delete itself, and only an administrator can remove staff.

In practice — Suspending an account is instant and does not affect the bills that person already handled.

Restaurant settings

Tax and service rates belong to the business, not to the software.

- Restaurant name, VAT rate and service charge are all editable, and apply to bills opened afterwards.
- Supports menus priced with VAT already included — the tax is shown separately rather than added on top.
- The restaurant name here is what prints on the receipt.

In practice — Changing a rate does not disturb bills already open, so nothing changes under a guest mid-meal.

Floor plan on the web

Owners can see the room without standing in it.

- Exactly the same information the servers see, so there is no second version of the truth.
- Useful for an owner covering more than one site, or working from the office.

In practice — Works in any modern browser with nothing to install.

Orders on the web

Follow the whole service from one screen.

- The same filters as the floor staff use, with more room to read them.
- Open any bill to review or correct it.

In practice — Refreshes automatically as bills are opened and settled.

Sign in on a computer

The same account works on every device.

- One set of credentials for phone, tablet and browser.
- Nothing to install on a manager's laptop — it is a web address.

In practice — New staff can be onboarded in the time it takes to create an account.

Why you can rely on it

How the system protects your revenue, and what is planned next

Designed around the places POS systems usually go wrong

Most point-of-sale problems are not dramatic failures. They are a bill that is a few satang out, a void nobody can account for, or a device showing yesterday's prices. Each of those was treated as a requirement rather than an afterthought.

- **Money is handled exactly**

All amounts are stored as whole units internally, which removes the rounding drift that creeps into systems using decimal arithmetic. A bill split three ways still balances.

- **The server is the source of truth**

Devices display totals, but the price charged is always calculated centrally. A tampered or out-of-date device cannot change what a guest pays.

- **Permissions are enforced, not just hidden**

Restricting a screen in the interface is only the first layer. Requests made directly to the system are checked again against the signed-in role.

- **Behaviour is checked automatically**

Eighty-two automated checks run against the system, including one that walks a complete service from seating a table to the sale appearing in the daily report.

Verified automatically

Area	Checks	What is covered
Server	36 checks	Run against a real database, including one check that walks a full service from seating a table through to the sale appearing in the daily report
Application	46 checks	Bill calculation, order handling, role permissions and screen behaviour

Planned next

- Thermal receipt printing over Bluetooth
- Offline mode, so a network outage does not interrupt service
- Moving tables, merging bills and splitting a bill per guest
- Ingredient stock deduction as dishes are sold
- Multi-branch support with consolidated reporting

What is not built yet is listed openly, because knowing the boundaries of a system matters as much as knowing its features.
